**CASE REPORT** 

# Surgical Treatment of Symptomatic Coiling or Kinking Internal Carotid Artery

Omer Tetik\*, Ismail Yurekli\*, Levent Yilik\*, Galip Akhan<sup>†</sup>, and Ali Gurbuz\*

Coiling of the artery is a rare morphologic entity most frequently described in the internal carotid artery. Herein we present two cases with symptomatic kinked internal carotid artery: one suffering from paresthesia of the right arm and speech disturbances and the other suffering from weakness of the left half of the body and speech disturbances. Both patients were treated surgically. None of the patients experienced any peri- or postoperative complications.

Key words: atherosclerosis, carotid artery, carotid elongation, coiling or kinking

C oiling of the artery is a rare morphologic entity most frequently described in the internal carotid artery (ICA) as a cause of cerebrovascular insufficiency or in association with carotid atherosclerosis.<sup>1</sup> In other arteries, coiling is rarely reported because it remains asymptomatic and has no clinical relevance.<sup>2</sup> Herein we present two cases with symptomatic kinked ICA that we operated on in our clinic.

## **Case Report**

Two patients underwent surgery in our department for symptomatic ICA kinking. These two patients were admitted to the Department of Neurology. One of these patients was a 46-year-old male suffering from paresthesia of the right arm and speech disturbances. His past medical history revealed dizziness when hyperextending the neck. Doppler ultrasound examination showed elongation of the left ICA with normal flow characteristics, confirmed as kinking by magnetic resonance angiography (Figure 1).

The other patient was a 53-year-old female suffering from weakness of the left half of the body and speech

Both patients were operated on under general anesthesia with endotracheal intubation. The kinked segment of the carotid artery was resected. The first patient underwent end-to-end anastomosis of the ICA. The other patient underwent end-to-side anastomosis of the ICA to the common carotid artery (CCA) below the level of bifurcation (Figure 3 and Figure 4). None of the

patients experienced any peri- or postoperative complications. One patient was discharged on the fourth postoperative day, whereas the other was discharged on the fifth day.

#### Comment

Whether surgically correcting symptomatic carotid elongation with coiling or kinking in the absence of an atherosclerotic lesion of the carotid bifurcation is effective in preventing stroke remains a controversial issue. Although there are numerous studies in the literature on carotid elongation with coiling or kinking in the absence of atherosclerotic lesion of the carotid bulb (isolated elongation), many doubts remain as to its etiology, clinical role, and best management.<sup>3</sup> The only aspect fully clarified concerns the terminology, introduced by Metz and colleagues<sup>4</sup> and Wiebel and Fields<sup>5</sup> in the 1960s: coiling is an elongation of the ICA in a restricted space, causing tortuosity and resulting in a C- or S-shape curvature or a circular configuration, and kinking is a variant of coiling, that is, an angulation of one or more segments of the ICA.

**Figure 3.** Operative view of kinking of the internal carotid artery (the first patient).

Figure 4. Operative view; kinked internal carotid artery resected and anastomosed to the common carotid artery (the first patient).

The etiology of these peculiar arterial modifications seems to be related to a congenital basis, which may become exaggerated with aging of the artery.<sup>6</sup>

Coiling of the carotid artery may produce luminal narrowing, which could lead to turbulent blood flow and subsequent intimal ulceration and embolization. Symptoms therefore could be similar to those caused by atherosclerotic disease of the carotid bifurcation, and patients may present with strokes, hemispheric transient ischemic attacks, or amaurosis fugax.<sup>1</sup> The kinked ICA may be clinically significant and cause cerebral infarction, even in the absence of atherosclerosis.<sup>7</sup> No ICA stenosis was detected before surgery in our patients, but there were symptoms of cerebrovascular insufficiency in both patients. In our second patient, the angiographic view resembled coiling rather than kinking, but intraoperative exposure revealed kinking. Anatomic reconstruction together with the correction and elimination of the affected segments of the carotid artery may prevent progressive cerebrovascular symptoms and is associated with a low morbidity and mortality rate.<sup>8</sup> For a symptomatic atherosclerotic carotid lesion with an associated angulated carotid artery, transection of the ICA at the bulb, with an incision almost longitudinal to the CCA, leaving a large hole in the CCA, may be preferred for endarterectomy. Then caudal end-to-side ICA reimplantation on the lateral wall of the CCA may be done.

The aim of this study was to analyze our experience in the surgical treatment of symptomatic ICA coiling or kinking. In follow-up, we did not observe any vascular complications and recurrent symptoms. Our results indicate that surgical correction of symptomatic ICA coiling or kinking can be performed with excellent postoperative relief of signs and symptoms.
